Human-LLM Co-Pilot

Language-Guided Shared Decision-Making for Intelligent Vehicles

Zhenwu Fang

Project brief

An overtaking request leaves choices about timing, smoothness and energy. This project connects language interpretation, driver feedback, preference updates and automated vehicle execution in a traceable loop.

Recorded simulation: logged local Qwen 9B output, scripted feedback and native vehicle states.

Driver input	Language	Preference update	Plan evaluation	Execution
Goal + feedback	Task / plan scope	Evaluation evidence	Time / energy	Native simulation

Two recorded interaction cases

1. A time constraint and richer feedback

A 30-second completion requirement is grounded and confirmed. Plan-bound acceptance and reason feedback updates evaluation before a 26-second maneuver is selected.

2. A comparison changes the selected alternative

A smoothness/energy instruction is followed by acceptance and relative preference feedback. The recorded branch selects a 29-second alternative under the original checks.

75-second video | Interactive first-person replay | Trajectory and decision events

Presentation uses selected simulation episodes. The static browser replay makes no live model calls.
